Invasive killer algae

Invasive algae is killing all the creatures in Vermont. not only killing off fish and a little bit of the land animals. It's because it's bringing invasive parasites, it's bringing invasive species of fish and other underwater aquatic creatures, and finally it's killing a few different species of land animals Including predators.

Different species of invasive parasites are getting into different fishes gills. It is causing them to get really sickly because these parasites don't eat other things like plants or meat they drink blood which can make a fish sick. These parasites can also be poisonous or cause many illnesses and these illnesses or poisons can affect humans.

Invasive species and organisms. These invasive species and organisms are causing great harm to the population of fish and the amount of fishing limits. Some of the invasive fish are predators. These Predators will eat the fish that are found in Vermont. When Predators eat the infected fish with parasites from the invasive algae they can get really sick which can cause the predators that eat this type of fish or this parasite they will get sick.

The death of many creatures in the water in Vermont is caused by the invasive algae. Because the invasive allergy is slowly causing other fish to be infected with parasites and attack by different predators that do not belong here, they are getting attacked and killed. The natural predators that eat the fish in the water can get sick from eating the infected fish which can cause a mass death of many creatures in Vermont from invasive algae.

That's why I think we should start cleaning our boat before going into the water. My three reasons are they are different species of parasites that do not belong to invasive species and organisms deadly to certain fish and large decline in certain types of fish .
